ABSTRACT

The topical application of phytojuvenoid on *Bombyx mori* larvae has been proved to be of biotechnological significance in the sericulture industry. Variation in the phytojuvenoid concentration significantly ($P_1 < 0.01$) influenced the total protein level in the fat body of larvae at the initial stage of spinning. The maximum level of total protein content was recorded in case of 30% phytojuvenoid concentration at triple treated (IIIth - IVth) larvae while it was lowest in 40% phytojuvenoid concentration at triple treated larvae at the initial stage of spinning. The phytojuvenoid influences the level of protein in the larvae and caused some beneficial effect on the life pattern of silkworm and the productivity of cocoon.

Key words: Phytojuvenoid, Protein content, Fat body, Larvae, *Bombyx mori*.

INTRODUCTION

Sericulture, or silk farming, is the rearing of silkworms for the production of silk. Although there are several commercial species of silkworms, *Bombyx mori* is the most widely used and intensively studied silkworm. Nistari is a resistant variety of multivoltine mulberry silkworm (*Bombyx mori*) which contributes up to a great extent in the

commercial production of cocoon. In order to increase, the production of silk, efforts have been made to study effect of ecological factor (Upadhyay et al., 2004.), photoperiod (Mishra and Upadhyay 1993) etc on the performance of silkworm. The Magnetization of eggs influences silk producing potential (Upadhyay and Prasad 2010a) and incubation period of eggs (Upadhyay and Prasad 2010b) and larval performance (Prasad and Upadhyay, 2011). The phytoecdysteroid and the juvenile hormone analogue has been noticed to influence the development, growth, silk producing and reproductive potential of *B. mori* (Pandey and Upadhyay, 2013; Srivastava and Upadhyay 2012, Srivastava and Upadhyay 2015). The synchronized maturation of larvae and simultaneous spinning of cocoon is very important in the sericulture industry. However, the response to such treatment varies depending on the dosage of compounds showing duration and number of applications (Chowdhary et al., 1990). The more food ingested during this period

gets converted and it turn contributes to silk protein. Delay in moulting is probably due to the inhibitory action of JH on ecdysone synthesis in *B. mori* (Trivedy et al., 1997). JH is claimed to inhibit protein synthesis in early treated larvae with later on region protein synthesis resulting in bigger silk gland and the result is improvement of cocoon shell weight (Garel, 1983). In the present study *Pinus longifolia* was taken for experiment due to its good availability and containing juvenile compound.

Material and Methods

The seed cocoons (pupa enclosed in silken case) of multivoltine mulberry silkworm (*Bombyx mori* nistari) were obtained from the silkworm grainage, Directorate of sericulture, Behraich Uttar Pradesh and were maintained in the plywood trays (23 x 20 x 5cm) under the ideal rearing conditions (Krishnaswamy et al. 1973) in the silkworm laboratory, Department of Zoology D.D.U. Gorakhpur University, Gorakhpur. The temperature and relative humidity were maintained at $26 \pm 1^\circ\text{C}$ and $80 \pm 5\%$ RH respectively till the emergence of moths from the seed cocoons. The newly emerged moths were quickly picked up and kept sex-wise in separate trays to avoid copulation. The male moths were smaller in size but more active than the female moths which were comparatively larger and less active. The whole grainage operation was performed as per description given by Krishnaswamy et al. (1973). Moths have a tendency to pair immediately after emergence, therefore, Sufficient pairs, each containing one male and one female from newly emerged moths were allowed to mate at $26 \pm 1^\circ\text{C}$ and $80 \pm 5\%$ RH in 12 hour / day dim light condition. After four hours of mating, the paired moths were detached manually. The female moths were allowed for egg laying. After 24 hours of egg laying, the female moths were individually examined for their disease freeness and after formaline treatment The dried eggs were transferred to the incubator for hatching. After hatching, the silkworm larvae were reared on the fresh and clean leaves of *Morus alba* given as food in the rearing trays.

These larvae were taken for the purpose of experiments. After completion of fifth instar, the ripe worms ceased feeding and ready for spinning. Small mountages were provided to the ripe worms and thus, sufficient number of cocoons was obtained from the silkworm larvae reared in our laboratory.

Design of Experiment

For extraction of phytojuvenoid the needle of *Pinus* were collected, washed thoroughly with distilled water and dried in incubator at 37°C . The dried materials were powdered separately with the help of mechanical device. Further, 50 gm powder was subjected to extraction separately through soxlet

apparatus with 250 ml distilled water for 40 hours. After 40 hours of extraction a little amount of concentrated solution of plant extract was obtained. The concentrated solution was dried and 6.45 gm material was obtained in powdered form. The dried powder thus obtained, was dissolved in distilled water as 5 gm in 25 ml water and used this solution for further experiment, as 100% concentration of phytojuvenoid. For further experiment the suitable narrow ranges of *Pinus* phytojuvenoid concentrations viz. 10, 20, 30 and 40% were taken. Thus, four phytojuvenoid concentrations were applied topically by spraying as 1 ml on to 100 larvae separately. Three sets of experiments were designed viz., single, double and triple treatment of larvae.

Single treatment of larvae:

Single treatment of larvae was performed at the initial stage of fifth instar larvae just after fourth moulting. One hundred larvae of fifth instar at the initial stage were taken out from the BOD incubator and treated with one ml of 10% concentrated solution of *Pinus* needle extract by sprayer.

Double treatment of larvae:

Double treatment of larvae was started from the initial stage of fourth instar larvae. In the first treatment, one hundred larvae of fourth instar were treated by 1 ml of 10% concentrated solution of *Pinus* needle extract by spraying. The treated larvae were then transferred in BOD incubator for rearing and development. Further, similar second treatment for the same larvae was given at the initial stage of fifth instar larvae. Thus, in double treatment, fourth and fifth instar larvae were treated.

Triple treatment larvae:

For triple treatment, the third instar larvae in the initial stage were separated from BOD incubator. In the first treatment one hundred, third instar larvae, were treated by 1 ml of 10% concentrated solution of *Pinus* needle extract by sprayer and kept in BOD for rearing. The second treatment of same larvae was done just after third moulting i. e. at the initial stage of fourth instar larvae and transferred in BOD incubator for rearing. Third treatment was given at the initial stage of fifth instar i.e. just after fourth moulting of the same treated larvae as earlier. Thus, in the triple treatment third, fourth and fifth instar larvae were treated.

Similar experiments were performed by 20, 30 and 40% concentrations of phytojuvenoid obtained from *Pinus* needle extract. A control set was always maintained with each set of experiment. To observe the effect of phytojuvenoid at various stages of *Bombyx mori* larvae on certain biochemical constituents like total protein contents in the silk gland, haemolymph and fat body of larvae at the initial stage of spinning, following methods were adopted:

Table 1a- Effect of phytojuvenoid treatment on the total protein content (µg/mg) in the fat body of *Bombyx mori* larvae at the initial stage of spinning.

Stage of treatment (Larval instar)	Phytojuvenoid concentration (%)					F ₁ -ratio n ₁ =4

Total protein content:

For the estimation of total protein content from fat body of larvae, the fifth instar larvae were dissected

in distilled water at the initial stage of spinning and 0.01gm tissue of fat body was taken. Protein content was estimated according to Lowery et al. (1951) as

modified by Singh and Agarwal (1989). In above tissue added 4.0 ml of 10% T.C.A. and prepared the homogenate separately. The homogenate, thus obtained, was centrifuged at the top speed (20,000 rpm) for 10 minutes. Further, the supernatant was discarded, washed the precipitate with 5% T.C.A., again centrifuged for 10 minutes and discarded the supernatant. The precipitate was again washed with 10% T.C.A., centrifuged and discarded the supernatant. The precipitate, thus obtained, was dissolved in 4 ml of 10 N NaOH. Now in 1 ml of diluted supernatant, 0.5 ml, of freshly prepared alkaline copper solution (Reagent C) was added. Reagent C was prepared by the addition of 50.9 ml, reagent A (2% sodium carbonate in 0.1 N NaOH) and 1 ml Reagent B (1% of sodium potassium tartrate, 0.5% copper sulphate, mixed in 1:1 ratio at the time of experiment), The reaction mixture was kept for 10 minutes at room temperature, then 0.5 ml of folin ciocalten reagent (diluted 1:2 ratio with distilled water at the time of experiment) was added and mixed thoroughly. Thirty minutes after this the blue colour developed which was measured at 600 nm. Six replicates of each experiment were made. Standard curves were prepared with different concentrations of Bovin serum albumen. The value of protein has been expressed as $\mu\text{g}/\text{mg}$ of respective tissues.

All the data obtained by the experiment were analyzed statistically by two-way ANOVA and Post-hoc test.

Results

The data given in table-1a clearly indicates that the phytojuvenoid concentration and number of larval treatment influenced the total protein content in the fat body of larvae at the initial stage of spinning. With the increasing number of larval treatment with 10, 20 and 30% phytojuvenoid concentration, total protein content in the fat body of larvae at the initial stage of spinning increased gradually and reached to the highest level of $20.33 \pm 0.12 \mu\text{g}/\text{mg}$ in case of triple treated larvae with 30% phytojuvenoid concentration. In case of larval treatment with 40% phytojuvenoid concentration, the total protein content in the fat body of larvae at the initial stage of spinning increased in single treated larvae but further increase in the number of the larval treatment caused decline in the total protein content in the fat body of larvae at the initial stage of spinning which reached to the lowest level of $16.20 \pm 0.24 \mu\text{g}/\text{mg}$ in triple treated larvae. The trend of increase in the total protein content in the fat body of larvae at the initial stage of spinning was almost of same fashion in 10, 20 and 30% phytojuvenoid concentration in relation to the number of larval treatment. Two-way ANOVA indicates that variation in the phytojuvenoid concentration caused significant ($P_1 < 0.01$) influence on the total protein content while number of larval treatment has no significant influence on the total

protein content in the fat body of larvae at the initial stage of spinning. The Post-hoc test (table-1b) shows significant group difference in total protein content in the fat body of larvae at the initial stage of spinning in between all group combinations except in 10 and 40% phytojuvenoid concentration in single treatment of larvae. In the double and triple treated larvae significant group difference in the total protein content was recorded in between all group combinations except in control and 40% phytojuvenoid concentration.

Discussion

The change in the phytojuvenoid concentration and number of larval treatment of *Bombyx mori* influenced the total protein content in the fat body of *Bombyx mori* at the initial of spinning. With the increase in number of larval treatment from single to triple, the protein content in the fat body at the initial stage of spinning increased in 10, 20 and 30% concentration while in 40% concentration, the declining tendency in the protein content was noticed up to triple treatment of larvae. The highest level of protein content was noticed to be $20.33 \pm 0.12 \mu\text{g}/\text{mg}$ in the fat body obtained from the triple treated larvae of 30% concentration (Table 1a). The fat body plays an important role in the protein synthesis (Chang, 1972) and high level of protein content has also been found in the larval fat body of *Dixippus morosus* (Janda and Soch, 1970). Some of the protein, originally synthesized in the fat body, was isolated from the 5th instar larvae of *Bombyx mori* (Price, 1969). In the pupal stage of grain moth (*Sitotroga cerealella*) four major proteins were lost from the haemolymph and sequestered by the fat body, where they serve as a store of amino acids to be used in the development of adult (Patel, 1972). JHA isolated from Bemchi (*Psoralea corylifolia*) increased the total protein content significantly in the fat body of *Bombyx mori* (Nair et al., 2009). The biological function of Three crystal structures of a lipoprotein (Bmlp7), a member of the 30 kDa lipoprotein family from mulberry silkworm (*Bombyx mori* L.) haemolymph, is unknown, but its structural homology to sugar-binding proteins suggests that, in analogy to other 30 kDa haemolymph lipoproteins, it could play a role as an anti-apoptotic factor or function in the immune response of the insect to fungal infections (Pietrzyk et al. 2012). The total protein content in the fat body of *Bombyx mori* increased significantly with increasing the strength of magnetic field from 1000-3000 Gauss but in 4000G it was decreased. The maximum was observed in 3000G (Tripathi, 2012)

As discussed, a number of factors influenced the utilization and synthesis of protein and the level of total protein content in different tissues of silkworm at varying stages of the development. In last phase of 5th instar when silk gland is ready for synthesizing the

silk fibers, the posterior silk gland cells synthesized large amount of fibroin. Such high protein synthetic activity implies coordinated functioning of all the elements of the cells machinery devoted to fibroin assembling and maturation. The variation in the number of larval treatment and phytojuvenoid concentration, extended the larval period and the larvae feed more mulberry leaves during extended period, causing such physiological and biochemical changes which may have influenced the synthesis and utilization of protein level in the fat body of *Bombyx mori* larvae. But 40% concentration generated stress response, causing general decline in the rate of protein synthesis.

Conflict of Interests:
